

# Trident Z RGB Software Tutorial

## Enable Lighting Control on ASUS X99 Motherboards

---

### Introduction

In order to allow and enable Trident Z RGB lighting control on X99 motherboards, a “DRAM SPD Write” function must be enabled. By default, ASUS X99 motherboards have this set to “Disabled”, so we will have to enable this function to use the Trident Z RGB software. At the time of writing, Gigabyte, MSI, and ASRock X99 motherboards have this option enabled by default.

Note: For best results, please make sure BIOS is updated to the latest version.

### Instructions

1. **Enter BIOS.** (Press the “DELETE” key while the system is booting to enter BIOS.)
2. Check and make sure you are in the “Advanced Mode”.
  - a. If you are in the “EZ Mode”, press the “F7” key to switch to the “Advanced Mode” menu.
3. Navigate to the “**Ai Tweaker**” tab.
4. Scroll down to find “**DRAM Timing Control**” and press “Enter”.
5. Scroll all the way down to the bottom inside the “DRAM Timing Control” menu, and you will see a “**DRAM SPD Write**” option.
6. Press “Enter” or “Page Up/Down” to select “**Enable**”.
7. Press “F10” key to save and exit the BIOS.
8. After rebooting into the Windows OS, the Trident Z RGB software should be able to detect the memory modules and allow you to set lighting effects.

[See next page for example images.]
